Introduction. Acute gastrointestinal (GI)
bleeding is a common problem,
occurring in the upper GI tract of
100–200 per 100 000 persons annually
and in the lower GI tract of 20.5–27.0
per 100 000 persons annually
(1). Although 80%–85% of cases of GI
bleeding resolve spontaneously, it can
result in massive hemorrhage and death
(2). Most causes of acute GI bleeding are
identifiable and treatable.

highlight areas of the body in radiographic contrast to their surrounding tissues. Contrast media enhance the optical density of the area under investigation so that the tissue/structure absorption differentials are sufficient to produce adequate contrast with adjacent structures, enabling imaging to take place.

Contrast media | Radiology Key

Gastrointestinal bleeding can fall into two broad categories: upper and lower sources of bleeding. The anatomic landmark that separates upper and lower bleeds is the ligament of Treitz, also known as the suspensory ligament of the duodenum. This peritoneal structure suspends the duodenojejunal flexure from the retroperitoneum. Bleeding that originates above the ligament of Treitz usually ...

the mainstay of initial investigations. Angiography and radionuclide imaging are best suited for acute overt gastrointestinal (GI) bleeding. Capsule endoscopy and deep enteroscopy play significant roles in the diagnosis of obscure GI bleeding, usually from the small bowel.

Diagnosis of gastrointestinal bleeding: A practical guide ...

Upper gastrointestinal bleeding (UGIB) is a common medical emergency, with a reported mortality of 2-10%. Patients identified as being at very low risk of either needing an intervention or death can be managed as outpatients. For all other patients, intravenous fluids as needed for resuscitation and red cell transfusion at a hemoglobin threshold of 70-80 g/L are recommended.
