Rotary drilling is a method of drilling that employs a sharp, rotational drill bit to bite its way through the earth's crust. It relies upon high rotational speeds and thrust without percussion to achieve the desired effect and outputs. In rotary drilling, the rock is made to fracture by means of a combination of "pull down" pressure on the bit and rotational power "torque".

One type that has been used to excavate circular holes consists of down-the-hole motors that drive

excavating cutters that rotate in a column of bentonite drilling slurry. The cutters are designed to gouge the soil from the bottom of the excavation and push it to the center of the excavation, where it is then sucked into a flexible return line with the slurry and transported to the surface.

Rotary technology uses a sharp, rotating drill bit and downward pressure to cut, or crush, through the subsurface. Impact energy is supplied to the drill bit from either an above ground or down hole impact hammer. This impact force aids in the drilling. Depending on the competency of the substrate, the drill casing is advanced as the hole is cut, keeping the hole open during drilling.
